

F5b Reliability on the val split — linear axes, 20 equal-width bins. Error bars are 95% Wilson intervals (asymmetric near 0 and 1); open markers are sparse bins (<100 rows). Dashed line is the base rate. $\chi^2_\lambda = \exp(-\chi^2/2)$ is a *p-value* under the correct-hit hypothesis, not a posterior, so it carries no prior and sits flat near that rate.
